# CS4048 — DATA SCIENCE

**Lecture 14 & 15**

October 15 & 17, 2025

Fall 2025

FAST – NUCES, CFD Campus

Dr. Rabia Maqsood

[rabia.maqsood@nu.edu.pk](mailto:rabia.maqsood@nu.edu.pk)

# TODAY'S TOPICS

- Inferential statistics role in data science
- Standard/sampling error
- Confidence interval
  - Significance level
  - z-test, t-test critical value
- Hypothesis/significance testing
  - Null & alternative hypothesis
  - Critical value
  - P-value
  - z-test, t-test, Chi-square test

# INFERENCE STATISTICS

- Objective is to make inferences based on sample data collected and draw conclusions about the population.
- Examples:
  - The average expectancy of life have declined over years in country X.
  - Men and Women have different average heights in a population.
  - Medicine B has a better effect on patients health than medicine A.
  - ...
- **More relevant to data science:**
  - What is the 95% confidence interval for predicted sales next month?
  - Is the mean squared error (MSE) improvement statistically significant?
  - Is the trend in monthly sales significant?
  - Does classifier A perform significantly better than classifier B?
  - Does showing recommendations increase average order value?
  - ...

# INFERENCE STATISTICS

- **Point estimate:** a single value that is used to estimate a population parameter
  - Example: estimating population mean (salary) based on a sample data
  - In data science, point estimate could be a model's accuracy measure (in classification).

# SAMPLING ERRORS

- Sampling error includes:
  1. **Systematic sampling error:** introduced by errors in data collection or data not drawn correctly (sampling bias), thus, the sample data is not a true representation of the population.
  2. **Random sampling error (or chance error or standard error):** variability in results occur due to a random chance
    - Samples drawn from the same population will rarely provide identical estimates of the population parameter of interest
- Systematic sampling error is the fault of the investigation, but random sampling error is not.

# STANDARD ERROR

- Standard error is a single metric that sums up the variability in the sampling distribution of a statistic.
- Even with the best sampling techniques, some degree of random error is expected.
- Standard error can be represented statistically to support inference results interpretation.
  - $S.E = \frac{\sigma}{\sqrt{n}}$
- **Statistical probability:** the probability associated with a statistic is the level of confidence that we have in an estimated value

# Chain of Reasoning for Inferential Statistics

*Are our inferences valid? ...Best we can do is to calculate probability about inferences*

# INFERENCE STATISTICS

- There are two forms of statistical inference:
  1. Confidence intervals
  2. Hypothesis (“significance”) tests

# CONFIDENCE INTERVAL

# CONFIDENCE INTERVAL (CI)

## Two forms of estimation

- **Point estimation**  $\equiv$  most likely value of parameter (e.g.,  $\bar{x}$  is point estimator of  $\mu$ )
- **Interval estimation**  $\equiv$  range of values with known likelihood of capturing the parameter, i.e., a **confidence interval (CI)**

# CONFIDENCE INTERVAL (CI)

- Confidence interval provides a level of uncertainty associated with the estimate and is expressed as a range of values.

- To calculate confidence interval, two elements are needed:

1. A statistic (or point estimate)
2. Level of confidence
3. Margin of error (denoted by E)

- Compute the confidence interval (CI) as:

Lower Bound of the Confidence Interval = Point Estimate – Margin of Error

Upper Bound of the Confidence Interval = Point Estimate + Margin of Error

# MARGIN OF ERROR (E)

- **Margin of error:** provides an indication of the maximum error of the point estimate (or test statistic)
  - A lower margin of error will increase our confidence in the point estimate
  - A higher margin of error will decrease our confidence in the point estimate
- **Margin of error (E) = Critical value \* Standard error**

Obtained from a data distribution,  
e.g., z or t distribution

$$\frac{\sigma}{\sqrt{n}}$$

# CONFIDENCE LEVEL

- In other words, the margin of error reflects the desired ***confidence level*** of the researcher.
- The confidence level is the **probability** that the interval estimate will contain the population parameter, given that the estimation process on the parameter is repeated over and over.
  - Example: A 95% confidence level means that if you were to take 100 different samples and create a 95% confidence interval (CI) for each one, you would expect 95 of those CIs to contain the true population value.
- CI is a range in which a true value is likely to be found with a certain probability.
- $CI = (1.0 - \alpha)$ , usually expressed as a percentage (e.g. 95%).
- For probability, we define a high confidence level usually 95% or 99% (or sometimes 90%).

Population  
 $\mu = \text{unknown}$   
 $\sigma = 40$

Calculate 95%  
confidence  
intervals

95% of these confidence  
intervals will capture  $\mu$

CI is a range in which a true value is likely  
to be found with a certain probability

Sampling distribution of  $\bar{x}$

# RESULTS INTERPRETATION

- Consider a data scientist who is interested in forecasting the median income for all residents of California. Income data is collected from a sample of 1,000 residents, and the median income level is \$68,500.
- Also assume the margin of error for a 95% confidence interval is \$4,500.
- Now the data scientist can construct a 95% confidence interval to forecast income levels as follows:

$$\begin{aligned}\text{Lower Bound of the Confidence Interval} &= \text{Point Estimate} - \text{Margin of Error} \\ &= \$68,500 - \$4,500\end{aligned}$$

$$\begin{aligned}\text{Upper Bound of the Confidence Interval} &= \text{Point Estimate} + \text{Margin of Error} \\ &= \$68,500 + \$4,500 = \$73,000\end{aligned}$$

- The data scientist can then state the following conclusion:
  - There is 95% confidence that the forecast for median income for all residents of California is between \$64,000 and \$73,000.

# “BODY WEIGHT” EXAMPLE

- Body weights of 20-29-year-old males have unknown  $\mu$  and  $\sigma = 40$
- Take an SRS of  $n = 712$  from population
- Calculate:  $\bar{x} = 183$

$$SE_{\bar{x}} = \frac{\sigma}{\sqrt{n}} = \frac{40}{\sqrt{712}} = 1.5 \text{ and } m \approx 2 \times SE_{\bar{x}} = 2 \times 1.5 = 3$$

95% CI for  $\mu \approx \bar{x} \pm m$

$$= 183 \pm 3$$

= 180 to 186 pounds

# CONFIDENCE INTERVAL FORMULA

Here is a more accurate and flexible formula

Critical value

$$\bar{x} \pm z_{1-\frac{\alpha}{2}} \cdot \frac{\sigma}{\sqrt{n}}$$

Equivalently,  $\bar{x} \pm z_{1-\frac{\alpha}{2}} \cdot SE_{\bar{x}}$

# Z TABLE

## Calculate Z-score for 95% confidence interval

| Z-score | 0.00   | 0.01   | 0.02   | 0.03   | 0.04   | 0.05   | 0.06   | 0.07   | 0.08   | 0.09   |

# COMMON LEVELS OF CONFIDENCE

| Confidence level | Alpha level | Z value            |
|------------------|-------------|--------------------|
| $1 - \alpha$     | $\alpha$    | $Z_{1-(\alpha/2)}$ |
| .90              | .10         | 1.645              |
| .95              | .05         | 1.960              |
| .99              | .01         | 2.576              |

# 90% CONFIDENCE INTERVAL FOR $\mu$

**Data:** SRS,  $n = 712$ ,  $\sigma = 40$ ,  $\bar{x} = 183$

$$\begin{aligned} 90\% \text{ CI for } \mu &= \bar{x} \pm z_{1-\frac{\alpha}{2}} \cdot \frac{\sigma}{\sqrt{n}} \\ &= 183 \pm 1.645 \cdot \frac{40}{\sqrt{712}} \\ &= 183 \pm 2.5 \\ &= 180.5 \text{ to } 185.5 \end{aligned}$$

# 95% CONFIDENCE INTERVAL FOR $\mu$

**Data:** SRS,  $n = 712$ ,  $\sigma = 40$ ,  $\bar{x} = 183$

$$\begin{aligned} 95\% \text{ CI for } \mu &= \bar{x} \pm z_{1-\frac{.05}{2}} \cdot \frac{\sigma}{\sqrt{n}} \\ &= 183 \pm 1.960 \cdot \frac{40}{\sqrt{712}} \\ &= 183 \pm 2.9 \\ &= 180.1 \text{ to } 185.9 \end{aligned}$$

# 99% CONFIDENCE INTERVAL FOR $\mu$

**Data:** SRS,  $n = 712$ ,  $\sigma = 40$ ,  $\bar{x} = 183$

$$\begin{aligned} 99\% \text{ CI for } \mu &= \bar{x} \pm z_{1-\frac{.01}{2}} \cdot \frac{\sigma}{\sqrt{n}} \\ &= 183 \pm 2.576 \cdot \frac{40}{\sqrt{712}} \\ &= 183 \pm 3.9 \\ &= 179.1 \text{ to } 186.9 \end{aligned}$$

# Z-DISTRIBUTION

- Use z-distribution when population SD is known and sample size  $\geq 30$

- Margin of error: 
$$E = z_c \frac{\sigma}{\sqrt{n}}$$

$z_c$  is called the critical value of the normal distribution and is calculated as the z-score, which includes the area corresponding to the confidence level between  $-z_c$  and  $+z_c$ . For example, for a 95% confidence interval, the corresponding critical value is  $z_c = 1.96$  since an area of 0.95 under the normal curve is contained between the z-scores of  $-1.96$  and  $+1.96$ .

$\sigma$  is the population standard deviation.

$n$  is the sample size.

# T-DISTRIBUTION

- Use **t-distribution** when population SD is unknown and smaller sample size  $< 30$  (t-distribution is based on degrees of freedom,  $df = n-1$ )

- Margin of error (E) is calculated as:

$$E = t_c \frac{s}{\sqrt{n}}$$

**Figure 4.3** Comparison of t-Distribution and Normal Distribution Curves

# T TABLE

**t Table**

| cum. prob | $t_{.50}$        | $t_{.75}$ | $t_{.80}$ | $t_{.85}$ | $t_{.90}$ | $t_{.95}$ | $t_{.975}$ | $t_{.99}$ | $t_{.995}$ | $t_{.999}$ | $t_{.9995}$ |

# HYPOTHESIS TESTING

Inferential Statistics: uses sample data to evaluate the credibility of a hypothesis about a population

NULL Hypothesis:

NULL (*nullus* - latin): "not any" → no differences between means

$$H_0 : \mu_1 = \mu_2$$

Always testing the null hypothesis

"H- Naught"

Inferential statistics: uses sample data to evaluate the credibility of a hypothesis about a population

Hypothesis: Scientific or alternative hypothesis

Predicts that there are differences between the groups

$$H_1 : \mu_1 \neq \mu_2$$

# Hypothesis

A statement about what findings are expected

null hypothesis

*"the two groups will not differ"*

alternative hypothesis

*"group A will do better than group B"*

*"group A and B will not perform the same"*

Alternative hypothesis is typically the statement that the researcher would like to prove or verify (i.e., researcher's claim).

# EXAMPLES

- Null = “no difference between the means of group A and group B”

Alternative = “A is different from B” (could be bigger or smaller)

- Null = “ $A \leq B$ ”

Alternative = “ $A > B$ ”

- Null = “B is not X% greater than A”

Alternative = “B is X% greater than A”

# WHY HYPOTHESIS TESTING?

- Why to perform a significance/hypothesis test when we can just compare the results and make a conclusion?
- For any single experiment, we are bound to see a difference, just as we see a difference between the means of two random samples in a distribution of sample means.
- If the null hypothesis is true, then differences in mean scores are just two random samples from the same population.
- Testing the null hypothesis: A statistical test assesses the probability of obtaining a given sample or samples of scores, assuming the null hypothesis is correct.

# HYPTHEESIS TESTING

If Null hypothesis is rejected, then we say that the result is **statistically significant**, for some level of significance( $\alpha$ ).

# Inferential Statistics

# Possible Outcomes in Hypothesis Testing (Decision)

|        | Null is True          | Null is False          |
|--------|-----------------------|------------------------|
| Accept | Correct Decision      | Error<br>Type II Error |
| Reject | Error<br>Type I Error | Correct Decision       |

Type II error: mistakenly concluding an effect is due to chance (when it is real)

Type I error: mistakenly concluding an effect is real (when it is due to chance)

Type I Error: Rejecting a True Hypothesis

Type II Error: Accepting a False Hypothesis

# TYPE I & II ERRORS

- Recall that hypothesis testing is performed to guard us in making a decision against a random chance.
- Thus, significance/hypothesis tests are typically structured to minimize Type I errors.
- Type II error is not so much an error as a judgment that the sample size is too small to detect the effect (i.e., a larger sample might yield the true effect).

# Hypothesis Testing - Decision

Decision Right or Wrong?

**But we can know the probability of being right or wrong**

**Can specify and control the probability of making TYPE I or TYPE II Error**

**Try to keep it small...**

## ALPHA

the probability of making a type I error  $\rightarrow$  depends on the criterion you use to accept or reject the null hypothesis = **significance level** (smaller you make alpha, the less likely you are to commit error) **0.05** (5 chances in 100 that the difference observed was really due to sampling error - 5% of the time a type I error will occur)

### Possible Outcomes in Hypothesis Testing

Alpha ( $\alpha$ )

Difference observed is really just sampling error  
The prob. of type one error

|        | Null is True          | Null is False          |
|--------|-----------------------|------------------------|
| Accept | Correct Decision      | Error<br>Type II Error |
| Reject | Error<br>Type I Error | Correct Decision       |

# WHEN NULL HYPOTHESIS IS TRUE (TYPE I ERROR)

- If null hypothesis is true and alpha level is set at .05, then the null hypothesis will be rejected 5% of time even though it is true.
- One way to safeguard against a Type I error is to set a more stringent alpha level (e.g.,  $p < .01$ ).

# SETTING THE PROBABILITY OF A TYPE I ERROR

- In trying to minimize, however, the probability of a Type I error, we encounter an **obstacle** in that the **probabilities of the Type I and Type II errors are inversely related**. Thus, if we try to make the probability of a Type I error very, very small, then it will make the probability of a Type II error quite large.
- As a compromise we therefore **specify a maximum tolerable Type I error probability**, called the **significance level, and denoted by  $\alpha$** , and choose the critical value  $C$  such that the probability of a Type I error is (at most) equal to  $\alpha$ .
- This  $\alpha$  is conventionally set to 0.10, 0.05, or 0.01.

## BETA

Probability of making type II error → occurs when we fail to reject the Null when we should have

### Possible Outcomes in Hypothesis Testing

Beta ( $\beta$ )

Difference observed is real  
Failed to reject the Null

|        | Null is True          | Null is False          |
|--------|-----------------------|------------------------|
| Accept | Correct Decision      | Error<br>Type II Error |
| Reject | Error<br>Type I Error | Correct Decision       |

POWER: ability to reduce type II error

POWER: ability to reduce type II error  
(1-Beta) - Power Analysis

The power to find an effect if an effect is present

1. Increase our  $n$
2. Decrease variability
3. More precise measurements

Effect Size: measure of the size of the difference  
between means attributed to the treatment

# HYPOTHESIS TESTING STEPS

- Hypothesis tests involve the following steps:
  1. State the null and alternative hypotheses
  2. Select a level of significance
  3. Choose a test criterion (z-test, t-test, chi-square, etc.) & state the decision rule
  4. Calculate the test statistic
  5. Make conclusion (reject or fail to reject the null hypothesis)

# 1. STATE HYPOTHESES: ONE WAY TEST

- One-way test: hypothesis test that counts chance results only in one direction.
  - One-tailed test predicts the direction of the effect or relationship
- Examples:
  1. RQ1: Does the new sales strategy increase average monthly revenue?
    - Null hypothesis ( $H_0$ ): The new strategy does not increase revenue. ( $\mu_1 \leq \mu_2$ )
    - Alternative hypothesis ( $H_1$ ): The new strategy increases revenue. ( $\mu_1 > \mu_2$ )
  2. RQ2: Does the new deep learning model achieve higher accuracy than the baseline model?
    - $H_0$ :  $\text{Accuracy}(\text{new}) \leq \text{Accuracy}(\text{baseline})$
    - $H_1$ :  $\text{Accuracy}(\text{new}) > \text{Accuracy}(\text{baseline})$

# 1. STATE HYPOTHESES: TWO WAY TESTING

- Two-way test: hypothesis test that counts chance results in two directions.
  - A.k.a two tailed hypothesis
- Examples:
  1. RQ1: Do male and female students differ in their average exam scores?
    - $H_0$ : The average exam scores are same for both genders ( $\mu_1 = \mu_2$ )
    - $H_1$ : The average exam scores are not same for both genders ( $\mu_1 \neq \mu_2$ )
  2. RQ2: Does changing the website layout affect conversion rate (in either direction)? (*A/B testing*)
    - $H_0$ : Conversion\_A = Conversion\_B
    - $H_1$ : Conversion\_A  $\neq$  Conversion\_B

**Generally, two-tailed tests are preferred to one-tailed tests.**

# ONE VS TWO TAILED TEST

# HYPOTHESIS TESTING STEPS

- Hypothesis tests involve the following steps:
  1. State the null and alternative hypotheses
  2. Select a level of significance
  3. Choose a test criterion (z-test, t-test, chi-square, etc.) & state the decision rule
  4. Calculate the test statistic
  5. Make conclusion (reject or fail to reject the null hypothesis)

## 2. LEVEL OF SIGNIFICANCE (ALPHA)

- In hypothesis testing, **significance** refers to when a result is very unlikely to have occurred if the null hypothesis is correct (type I or False Positive error).
- Alpha is the highest value of  $p$  that we are willing to tolerate and still say that a difference, change, or effect observed in the sample is "Statistically Significant"
- Set the fixed **alpha level** (Type I error) to 0.05. This means, **if the null hypothesis is true**, the probability of incorrectly rejecting it is 5% or less.

# HYPOTHESIS TESTING STEPS

- Hypothesis tests involve the following steps:
  1. State the null and alternative hypotheses
  2. Select a level of significance
  3. Choose a test criterion (z-test, t-test, chi-square, etc.) & state the decision rule
  4. Calculate the test statistic
  5. Make conclusion (reject or fail to reject the null hypothesis)

# 3. CHOOSE TEST CRITERION & DECISION RULE

## STATISTICAL TESTS CHEAT SHEET

The most commonare: z-test, t-test, f-test, chi-square

# 3. CHOOSE TEST CRITERION & DECISION RULE

The most common are: z-test, t-test, f-test, chi-square

# 3. CHOOSE TEST CRITERION & DECISION RULE

| Test statistic | Associated test  | Sample size                                   | Information given                                                                                                                                                          | Distribution | Test question                                                 |
|----------------|------------------|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|---------------------------------------------------------------|
| z-score        | z-test           | Two populations or large samples ( $n > 30$ ) | <ul style="list-style-type: none"><li>• Standard deviation of the population (this will be given as <math>\sigma</math>)</li><li>• Population mean or proportion</li></ul> | Normal       | Do these two populations differ?                              |
| t-statistic    | t-test           | Two small samples ( $n < 30$ )                | <ul style="list-style-type: none"><li>• Standard deviation of the sample (this will be given as <math>s</math>)</li><li>• Sample mean</li></ul>                            | Normal       | Do these two samples differ?                                  |
| f-statistic    | ANOVA            | Three or more samples                         | <ul style="list-style-type: none"><li>• Group sizes</li><li>• Group means</li><li>• Group standard deviations</li></ul>                                                    | Normal       | Do any of these three or more samples differ from each other? |
| chi-squared    | chi-squared test | Two samples                                   | <ul style="list-style-type: none"><li>• Number of observations for each categorical variable</li></ul>                                                                     | Any          | Are these two categorical variables independent?              |

# 3. HYPOTHESIS TESTING DECISION

- The decision to reject or not reject the null hypothesis usually is made with reference to the **sampling distribution of a statistic** of some kind (e.g., z-distribution, t-distribution).
- To make a decision whether to reject the null hypothesis, a **test statistic** is calculated.
- There are two approaches how to arrive at that decision:
  1. The critical value approach
  2. The p-value approach

# 3. HYPOTHESIS TESTING DECISION USING CRITICAL VALUE

- Critical value is a cut-off value that is used to mark the start of a region where the test statistic, obtained in hypothesis testing, is unlikely to fall in.
- The critical value divides the area under the probability distribution curve in **rejection region(s)** and **non-rejection region**.
- **Decision rule:**
  - If the test statistic  $>$  critical value  $\rightarrow$  **reject** the null hypothesis
  - If the test statistic  $\leq$  critical value, **fail to reject** the null hypothesis

# 3. HYPOTHESIS TESTING DECISION USING CRITICAL VALUE

- **How to compute critical value?**
  - The critical value is computed based on the given significance level  $\alpha$  and the type of probability distribution of the idealized (or null) model.
- We've already done this in confidence interval

TODO: Find critical value for a two-tailed z-test with  $\alpha=0.01$

# Z TABLE

z distribution a.k.a “standard normal distribution”
